An entire unit test that passes all of the test cases it has and appears valid, but upon closer inspection it is discovered that it doesn't really test the intended target at all.

Example	Cause	Solution
passes all tests with no useful assertions (aka: Line Hitter)	chasing test coverage not practicing test-first approach	add meaningful assertions or delete the test
test method name and test method content do not match	refactoring, but somehow the tests are still green not practicing test-first approach	keep test method names and test method content in sync

The Enumerator

A unit test with each test case method name is only an enumeration, i.e. test1, test2, test3. As a result, the intention of the test case is unclear, and the only way to be sure is to read the test case code and pray for clarity.

The Happy Path

A unit test that only tests the expected behaviour, not testing any boundaries or exceptions. The anti-pattern here is when the developer stops at happy path tests.

The Happy Path

Example	Cause	Solution
only one test per unit	not practicing test-first approach	start using test-first and start with testing the boundaries, using some
test only trying to prove the correctness of the business logic/	not testing boundaries	out of boundary values
algorithm		consider using Mutation Testing

A test that requires a lot of work setting up in order to even begin testing. Sometimes several hundred lines of code is used to setup the environment for one test, with several objects involved, which can make it difficult to really ascertain what is tested due to the "noise" of all of the setup going on.

Example

lots of mocked dependencies

lots of code to form a scenario

always set up the whole application context, instead of using only what is needed

Cause

tested class or method do too much, poor separation of concerns

tests and code are highly coupled

not practicing test-first approach

not practicing object calisthenics

Solution

start improving abstraction and separation of concerns

practice test-first

practice object calisthenics

A unit test that, although it is validly testing the object under test, can span thousands of lines and contain many many test cases. This can be an indicator that the system under tests is a God Object

Giant

Example

test with many lines of code, it takes ages scrolling the test and nothing can be found

tests with comment lines separating different sections within the test class

Cause

its easy to put everything in one class to keep dependencies low

a util class to collect all util methods used within the program, no matter where they are used

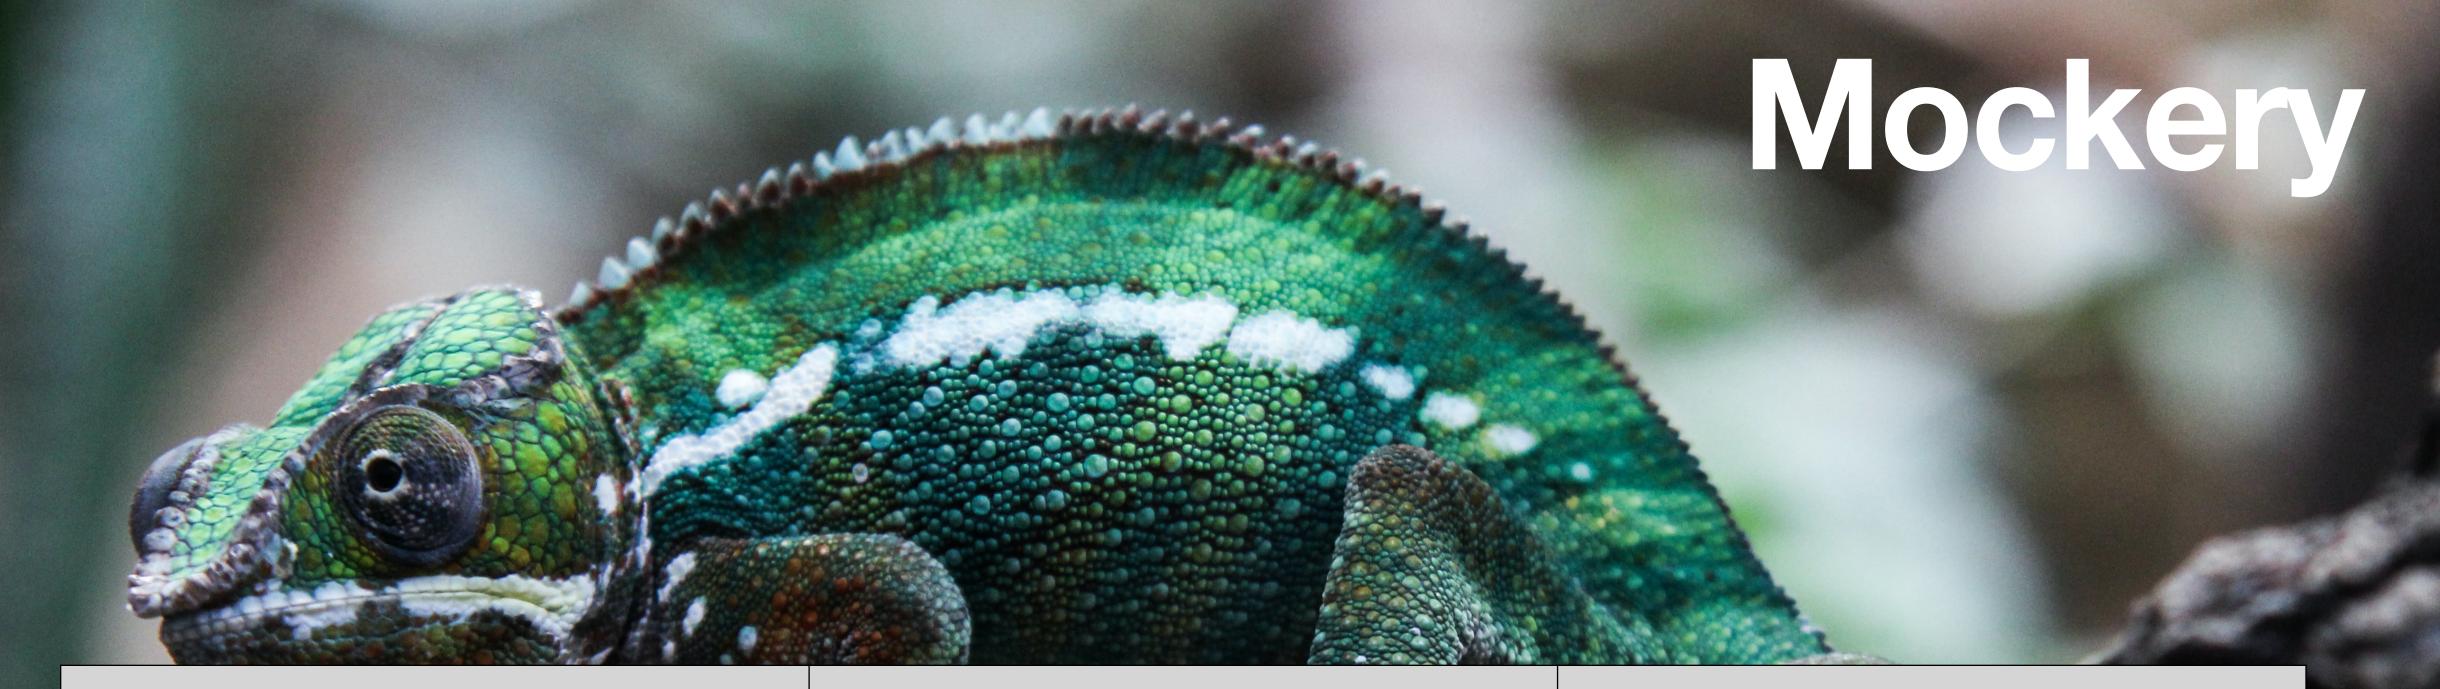

Solution

refactoring the tested class to several classes with separate concerns

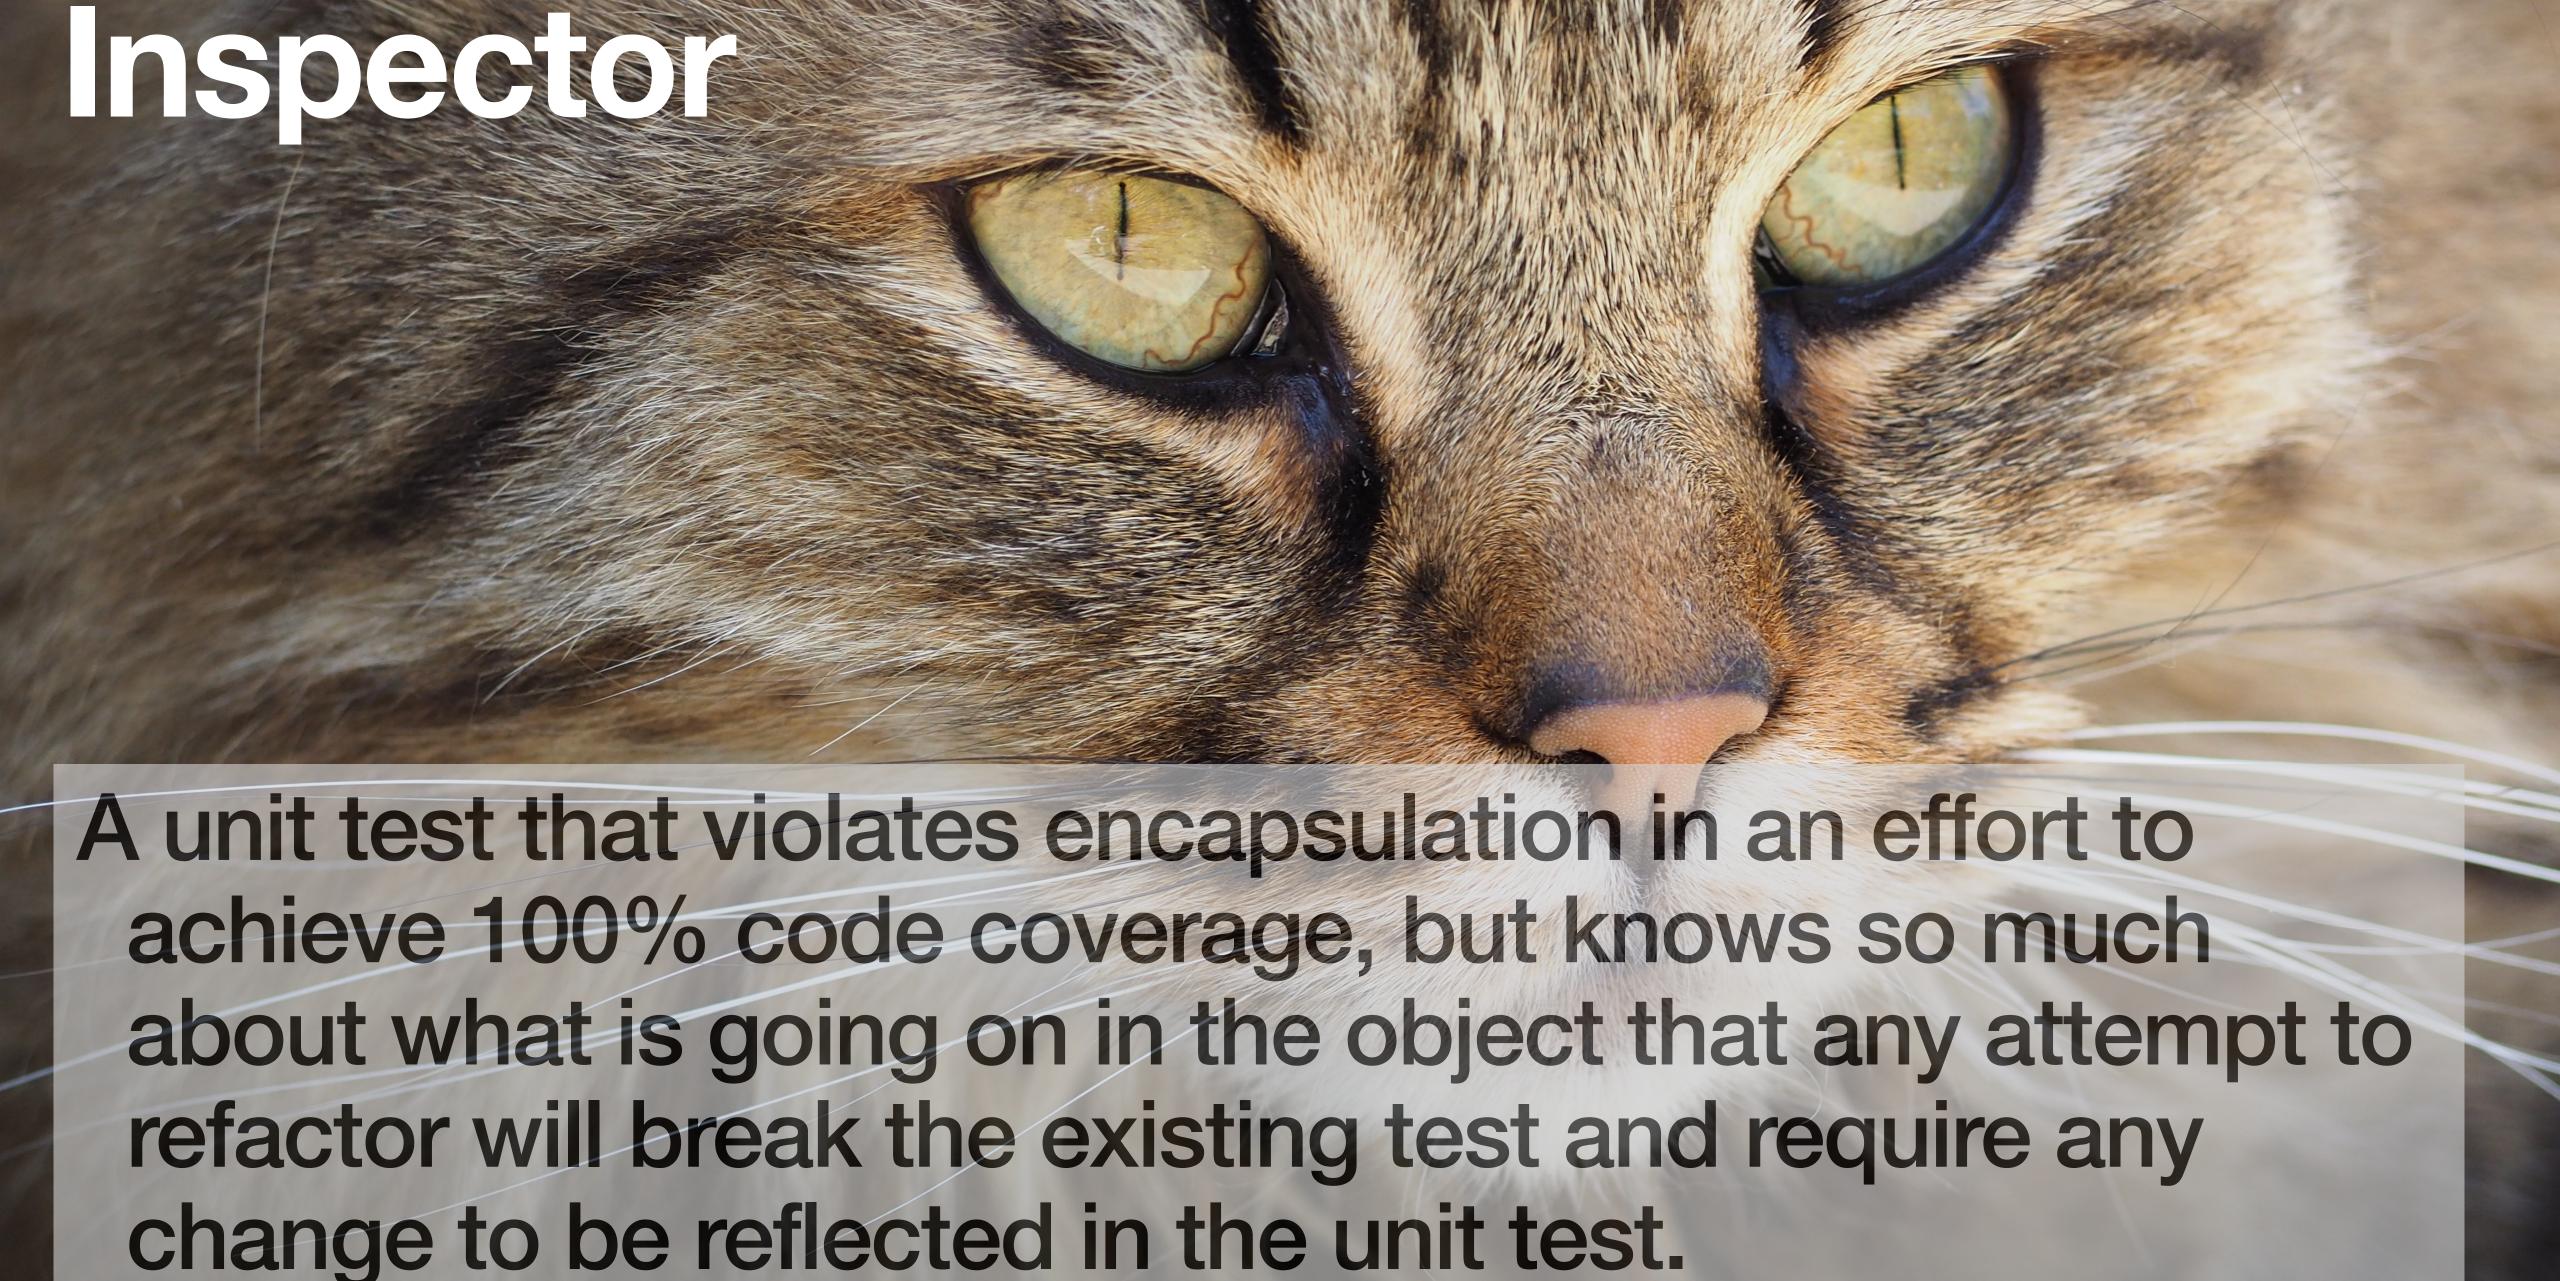

practice object calisthenics

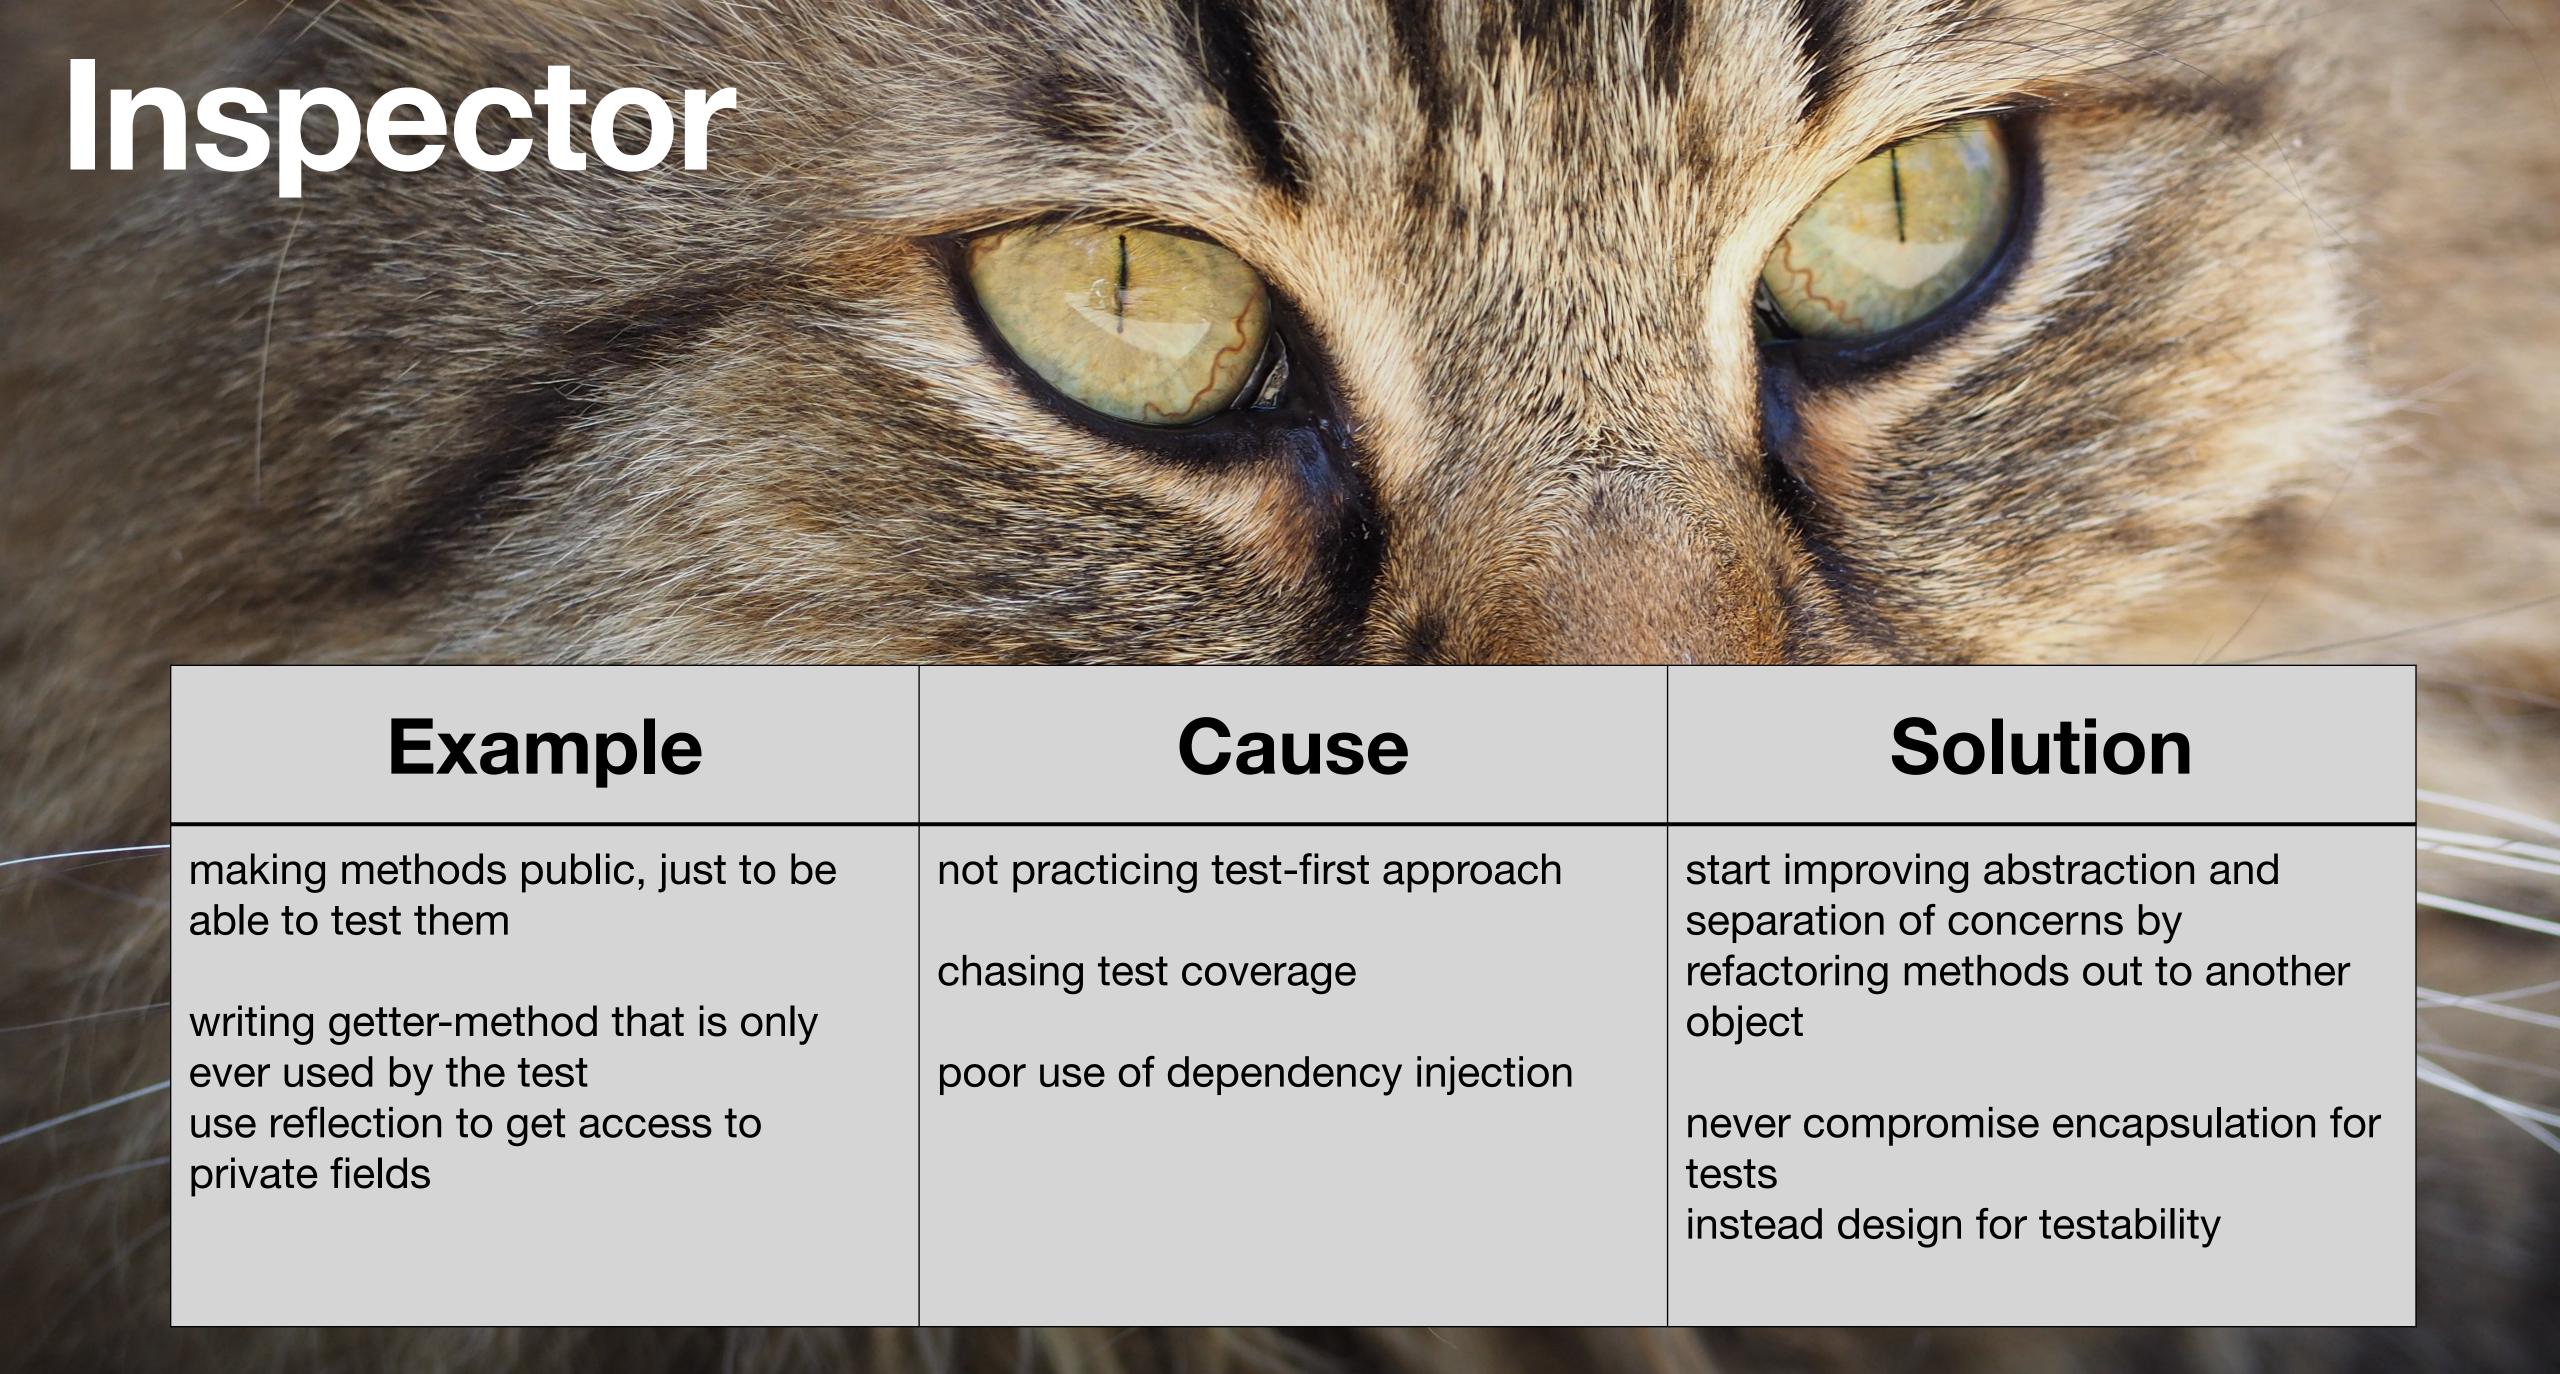

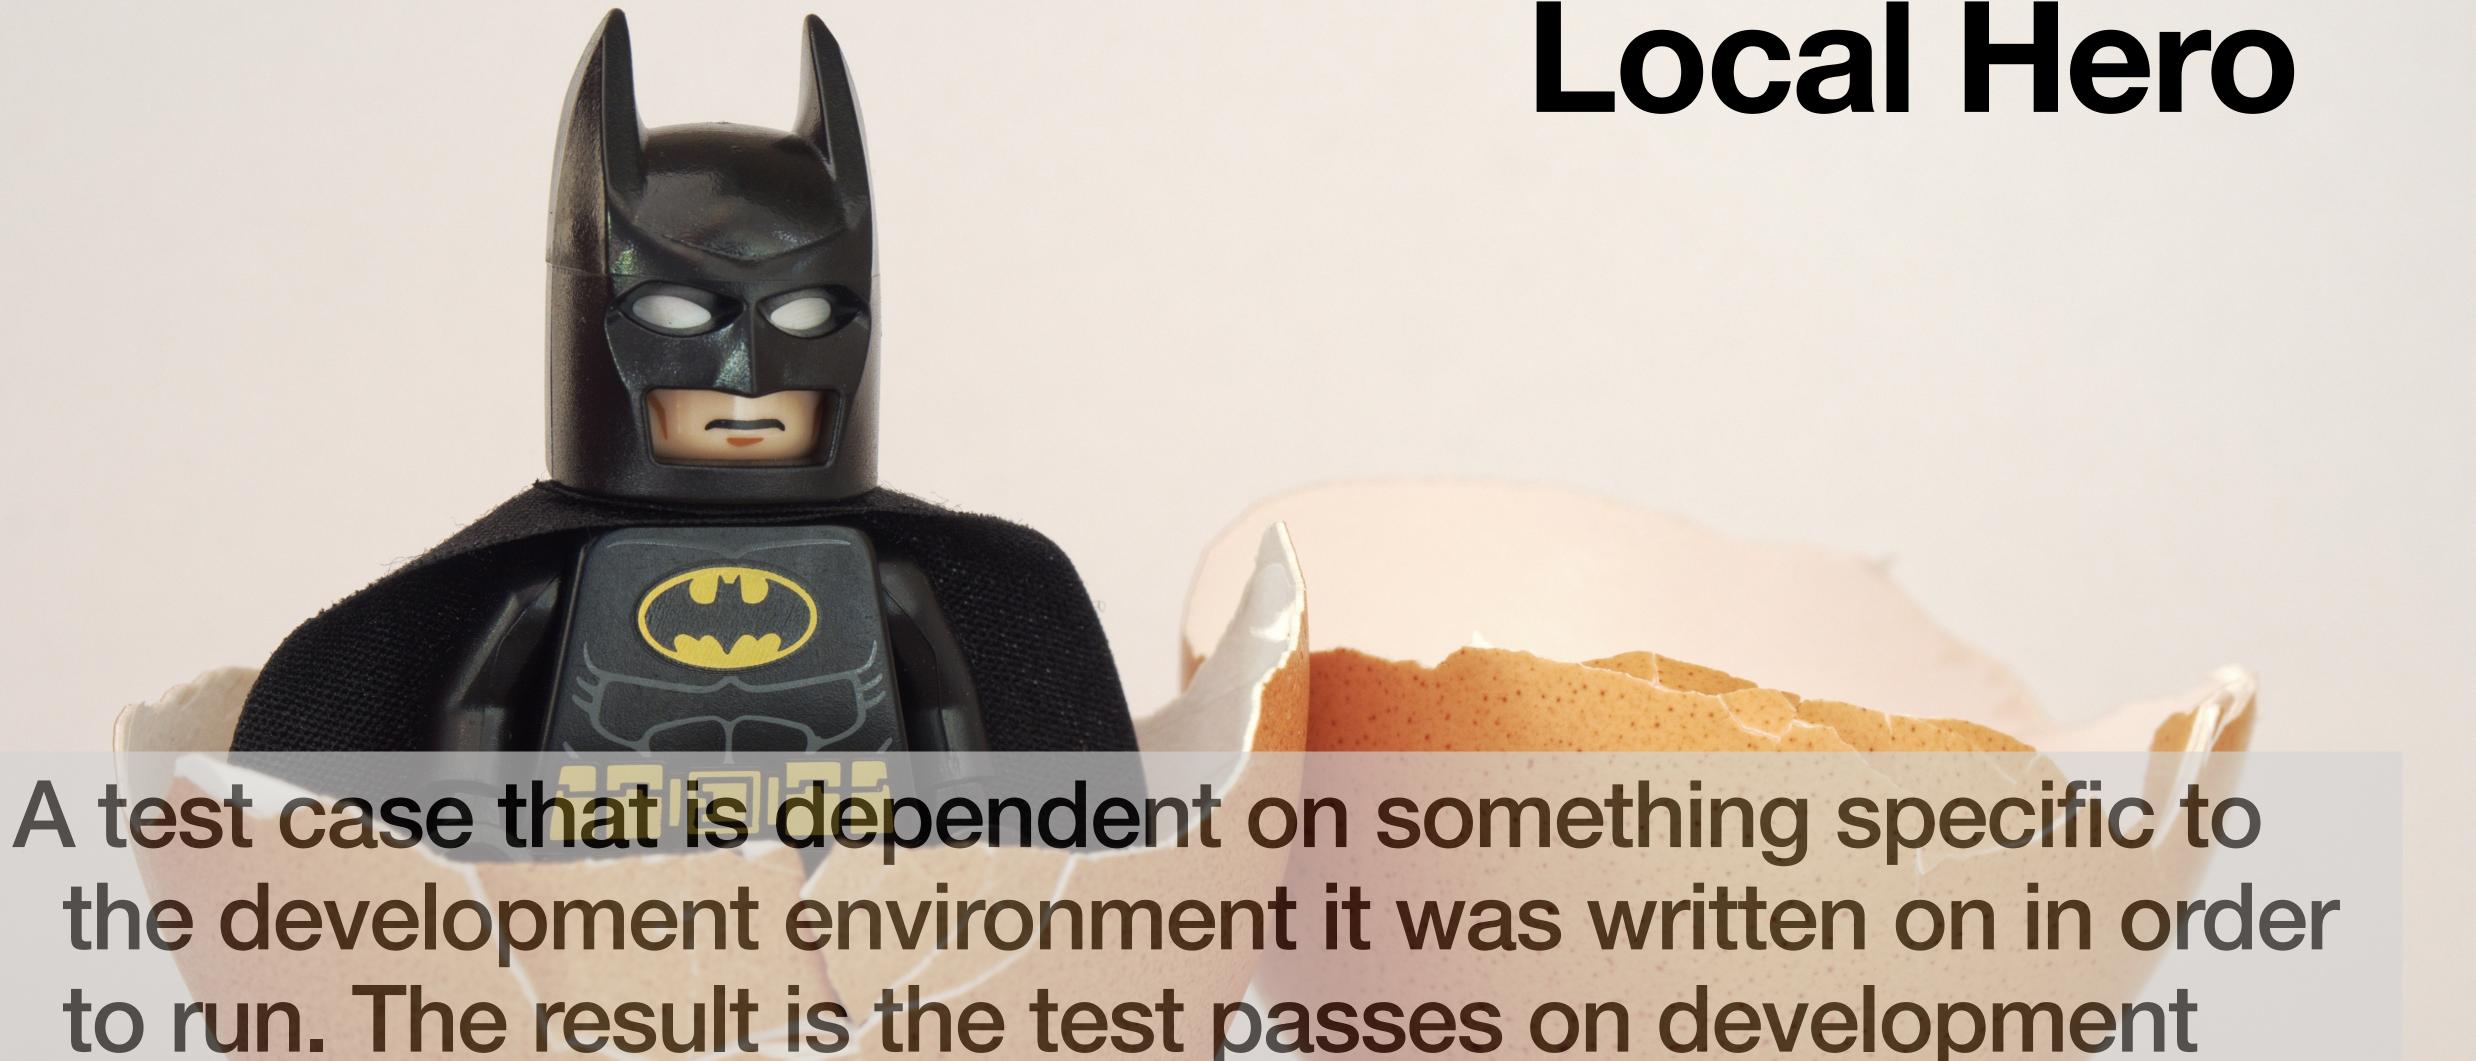

Sometimes mocking can be good, and handy. But sometimes developers can lose themselves and in their effort to mock out what isn't being tested. In this case, a unit test contains so many mocks, stubs, and/or fakes that the system under test isn't even being tested at all, instead data returned from mocks is what is being tested.

Example Solution Cause lots of dependencies that need possibly refrain from using mocking class under test contains methods frameworks and write your own mocking to isolate the code to test that do not really belong there and therefore have to be mocked Mocks, Stubs, Fakes, Test-Doubles (which will make you think about even partially mocking the class under test tests and code are highly coupled mocking) refactoring to less dependencies see: Excessive Setup using abstraction ans separation of concerns

boxes, but fails when someone attempts to run it

elsewhere.

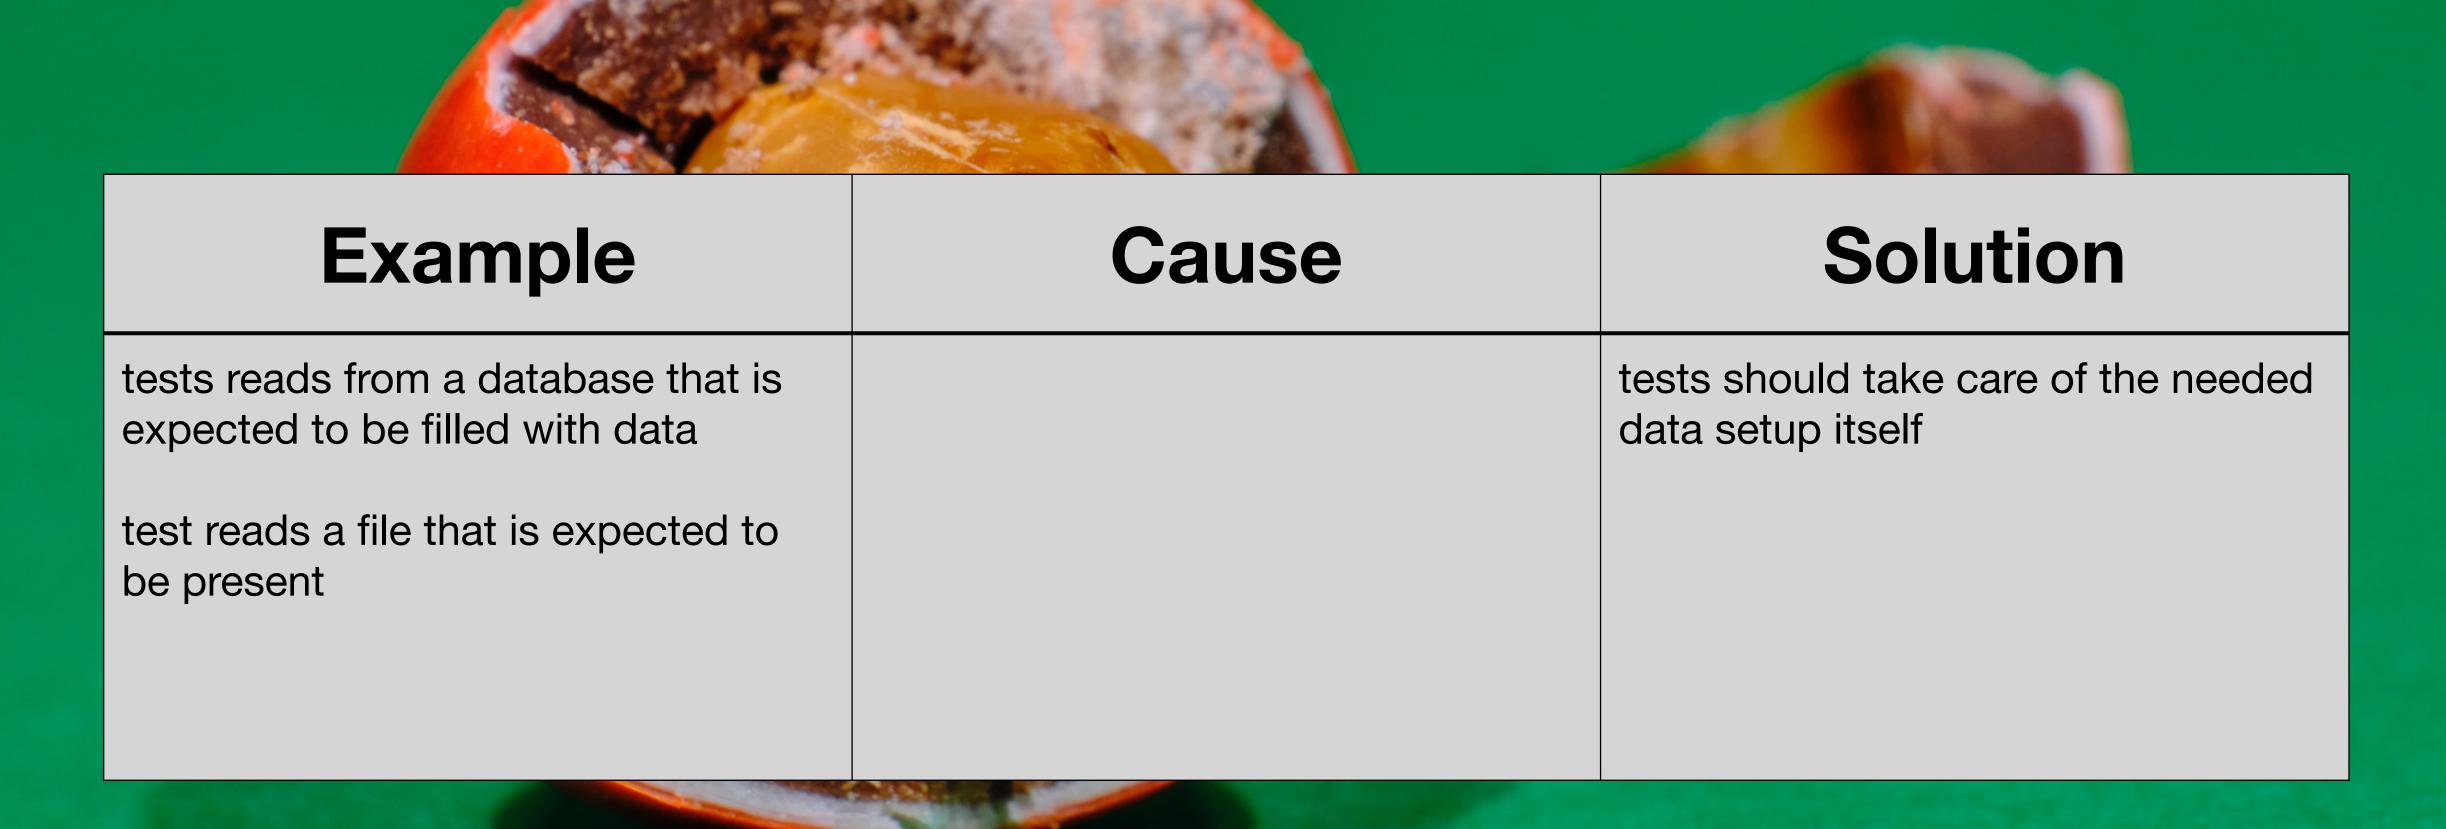

Local Hero

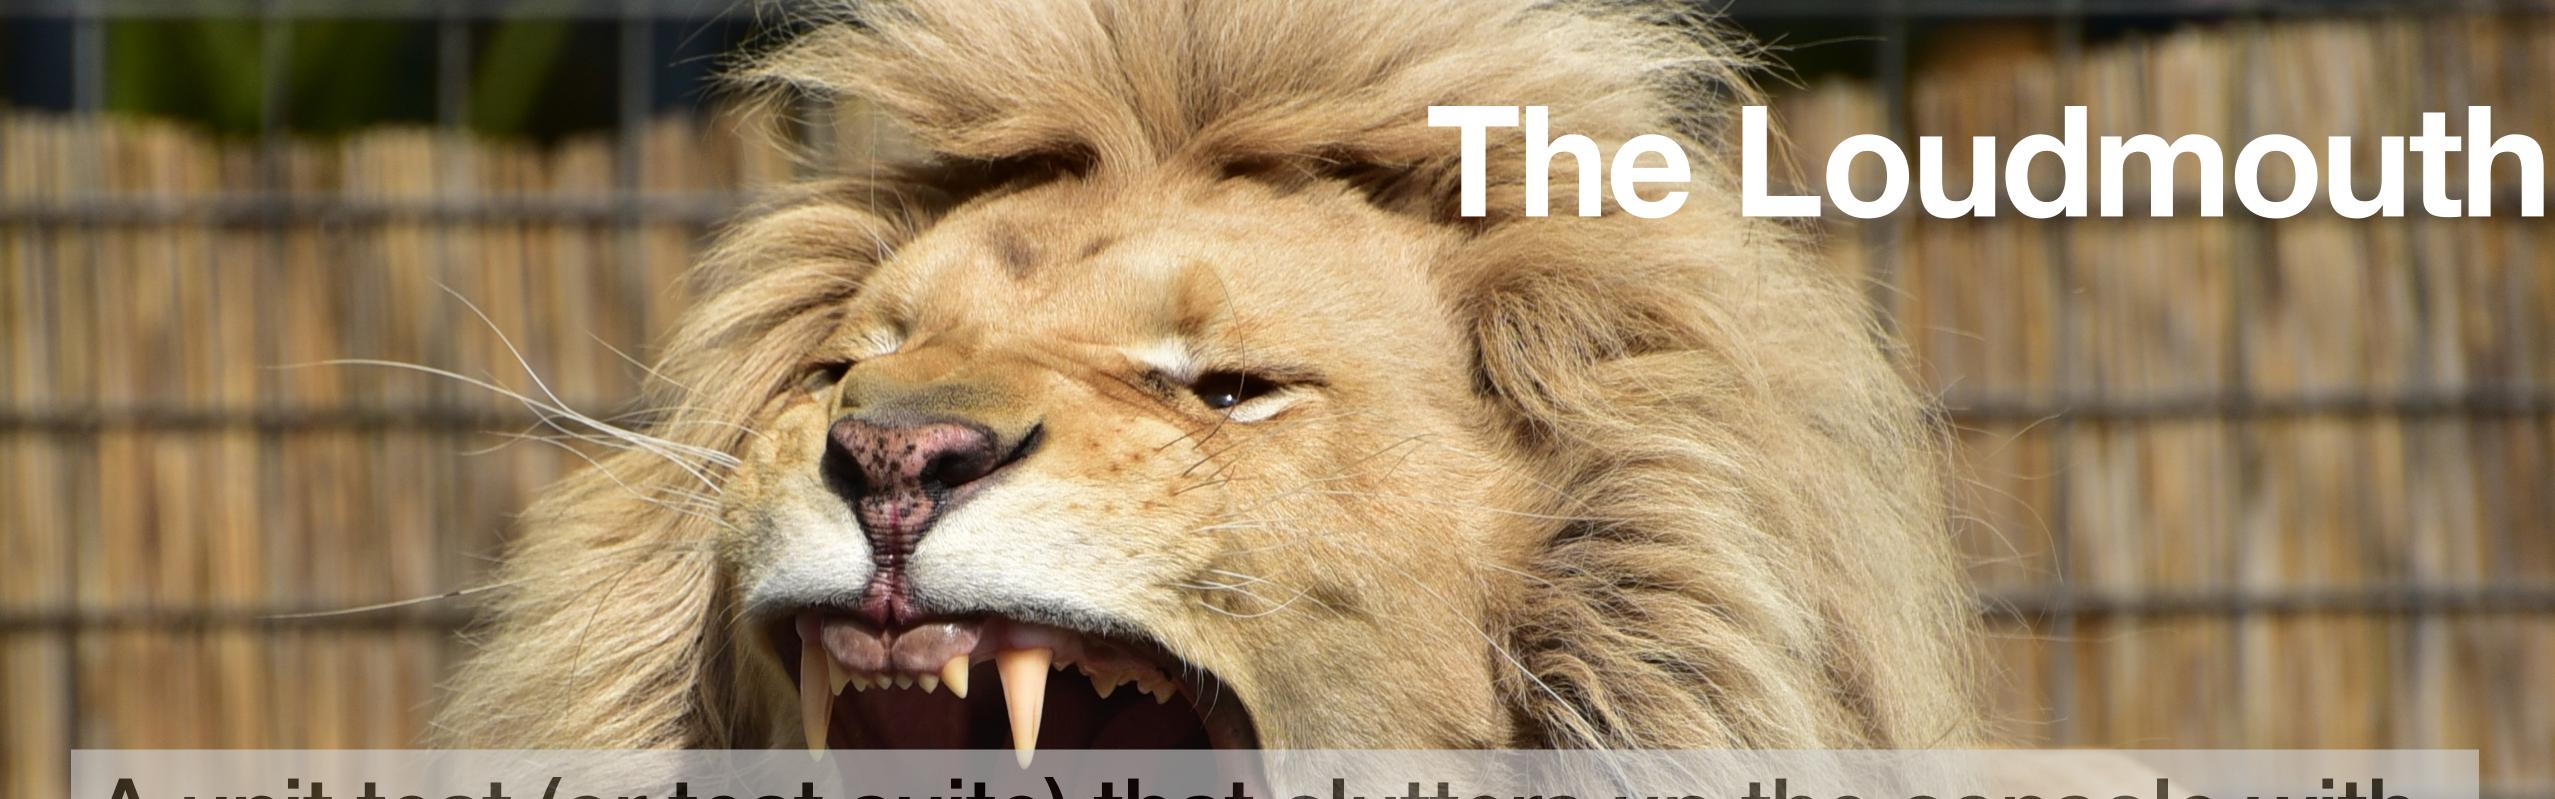

Example	Cause	Solution
using OS specific settings (i.e. line breaks) in tests	being unaware of build on different machines or OS	for instance: consistently use UTF-8
relying on some tool installed locally (databases,)	being unaware of usage of a local tool	possibly use tool libraries instead of the tool itself
		use In-Memory databases or Testcontainers

The Hidden Dependency

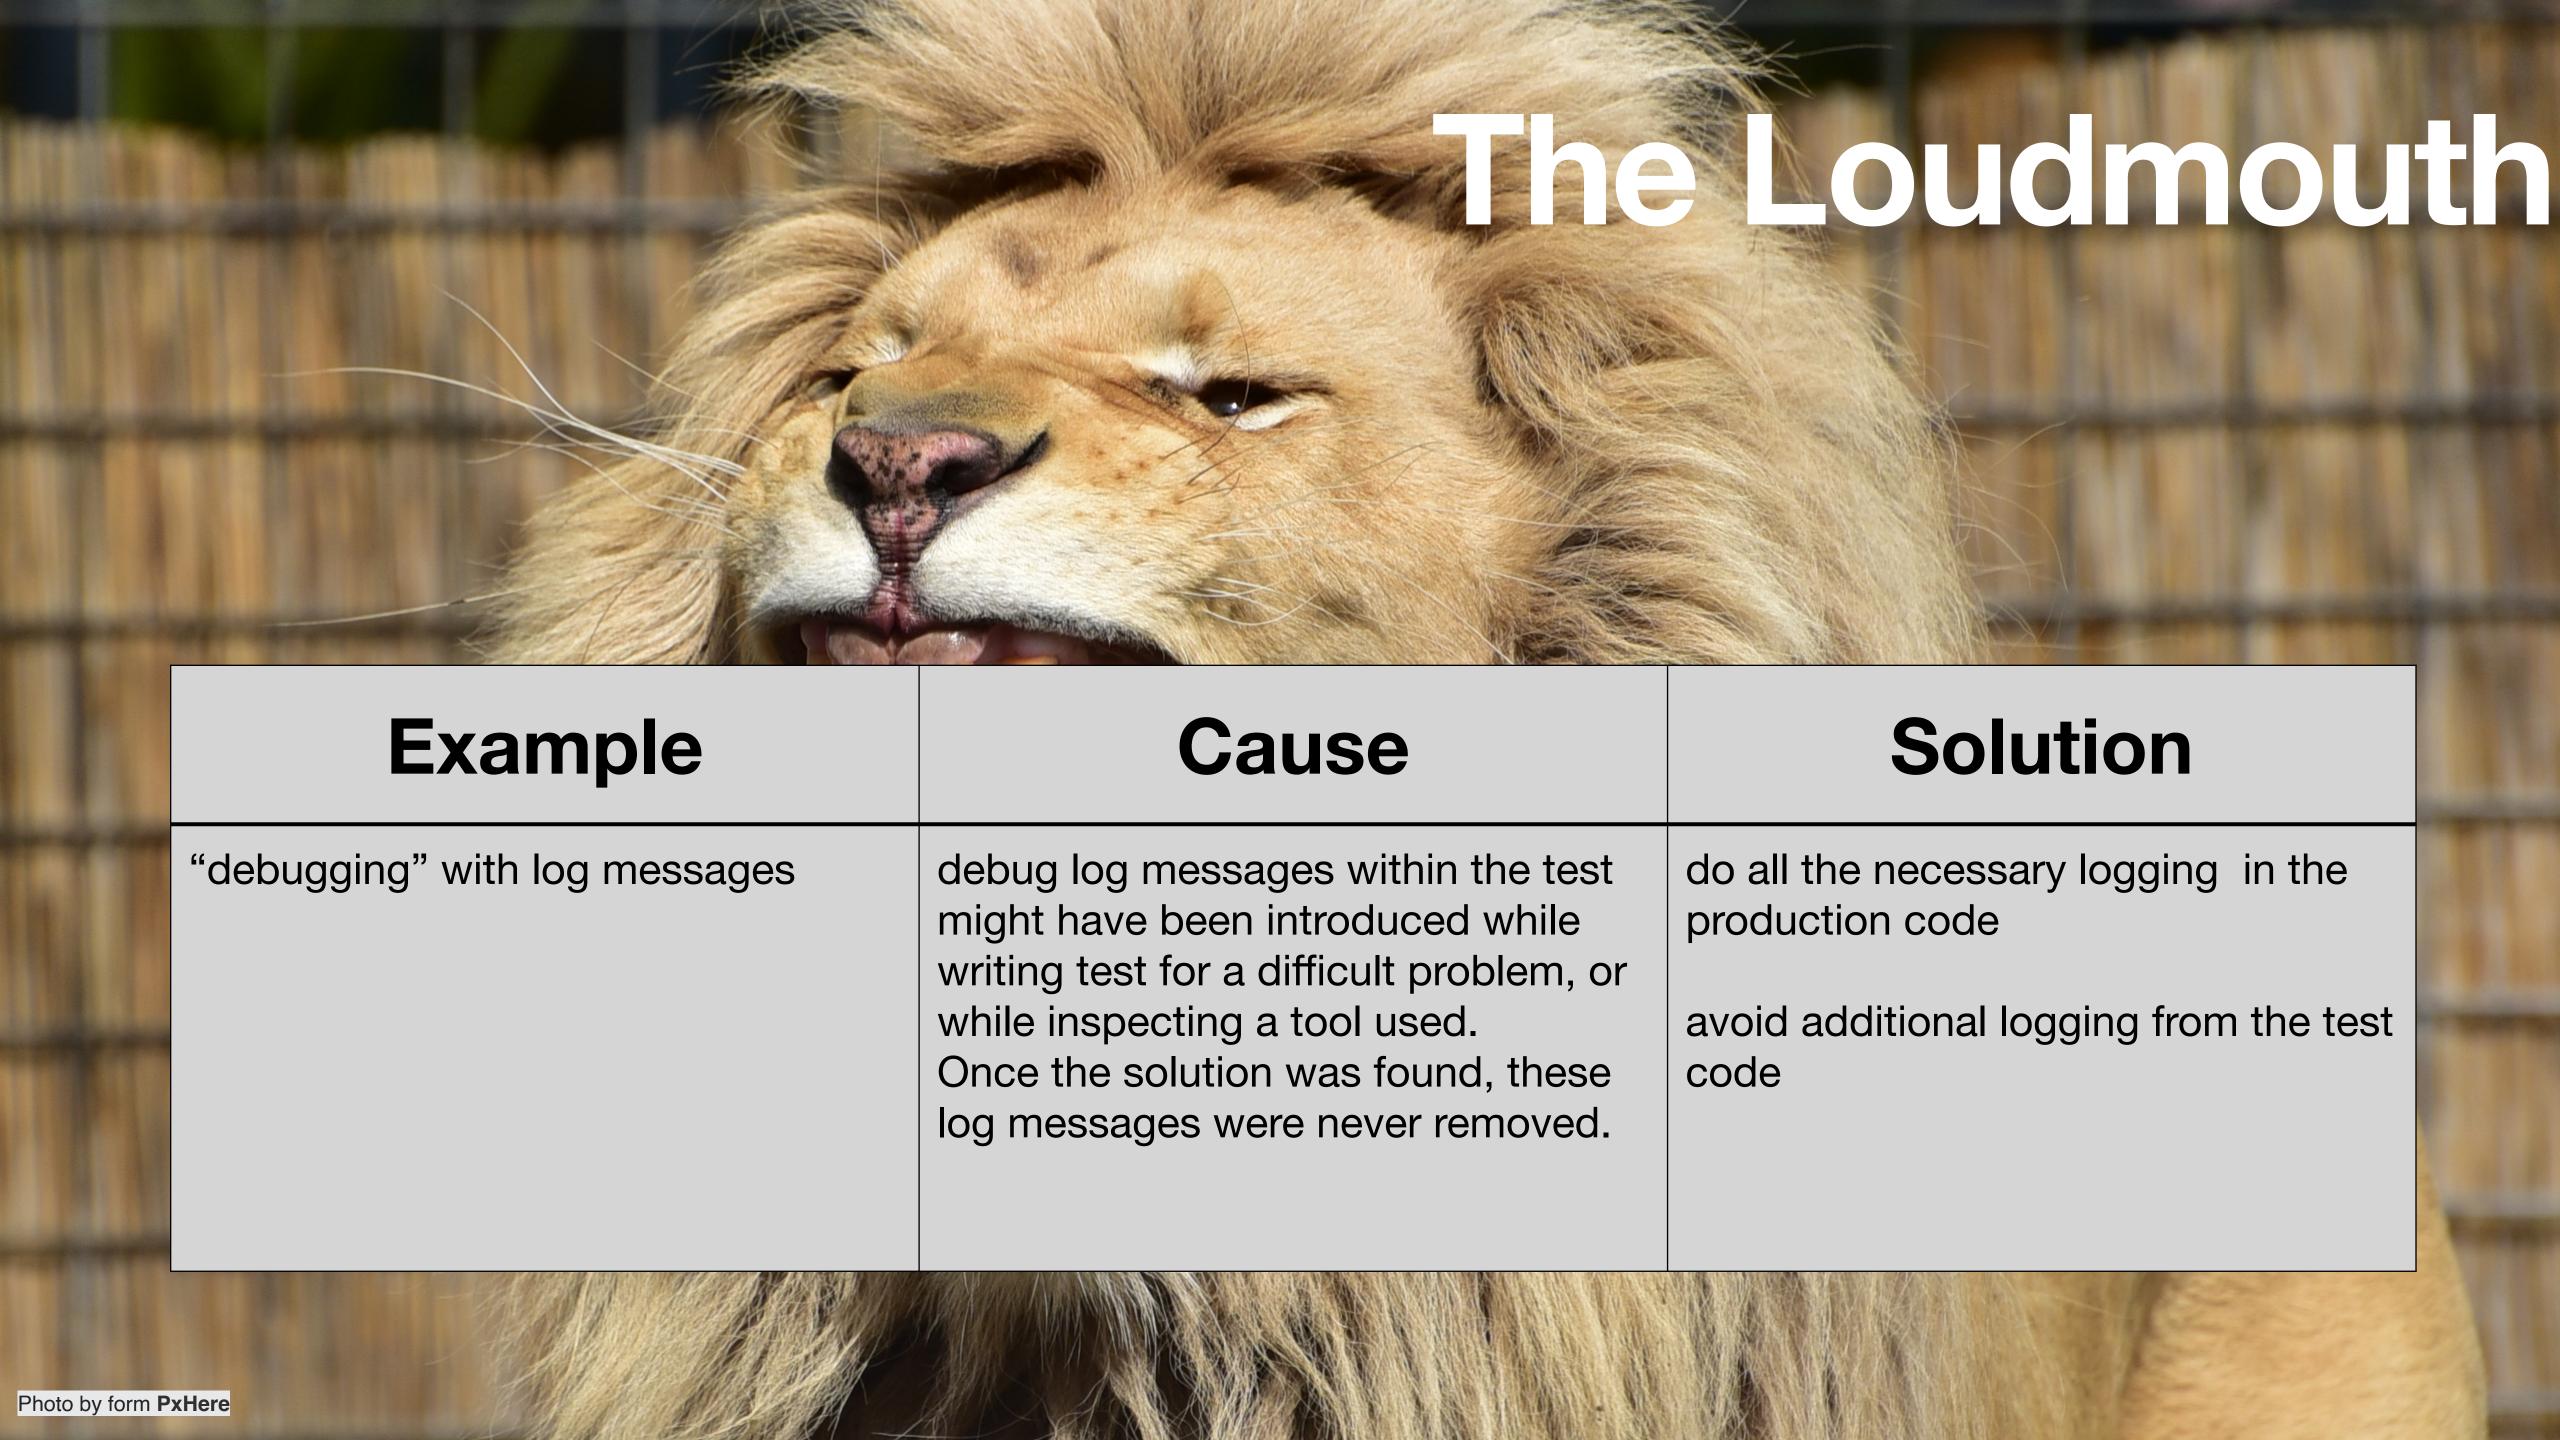

A close cousin of The Local Hero, a unit test that requires some existing data to have been populated somewhere before the test runs. If that data wasn't populated, the test will fail and leave little indication to the developer what it wanted, or why... forcing them to dig through acres of code to find out where the data it was using was supposed to come from.

The Hidden Dependency

A unit test (or test suite) that clutters up the console with diagnostic messages, logging messages, and other miscellaneous chatter, even when tests are passing. Sometimes during test creation there was a desire to manually see output, but even though it's no longer needed, it was left behind.

The Slow Poke

A unit test that runs incredibly slow. When developers kick it off, they have time to go to the bathroom, grab a smoke, or worse, kick the test off before they go home at the end of the day.

The Slow Poke

Solution Example Cause consider using less input data testing a time-consuming algorithm algorithm need lots of CPU-power with all possible inputs covering the boundaries and one or two happy paths in case of asynchronous setup, timeout are too long if another asynchronous test that waits for an system does not answer if making these tests faster is not answer possible, then run them less often (after careful consideration)

The Secuencer

A unit test that depends on items in an unordered list appearing in the same order during assertions.

The Secuencer

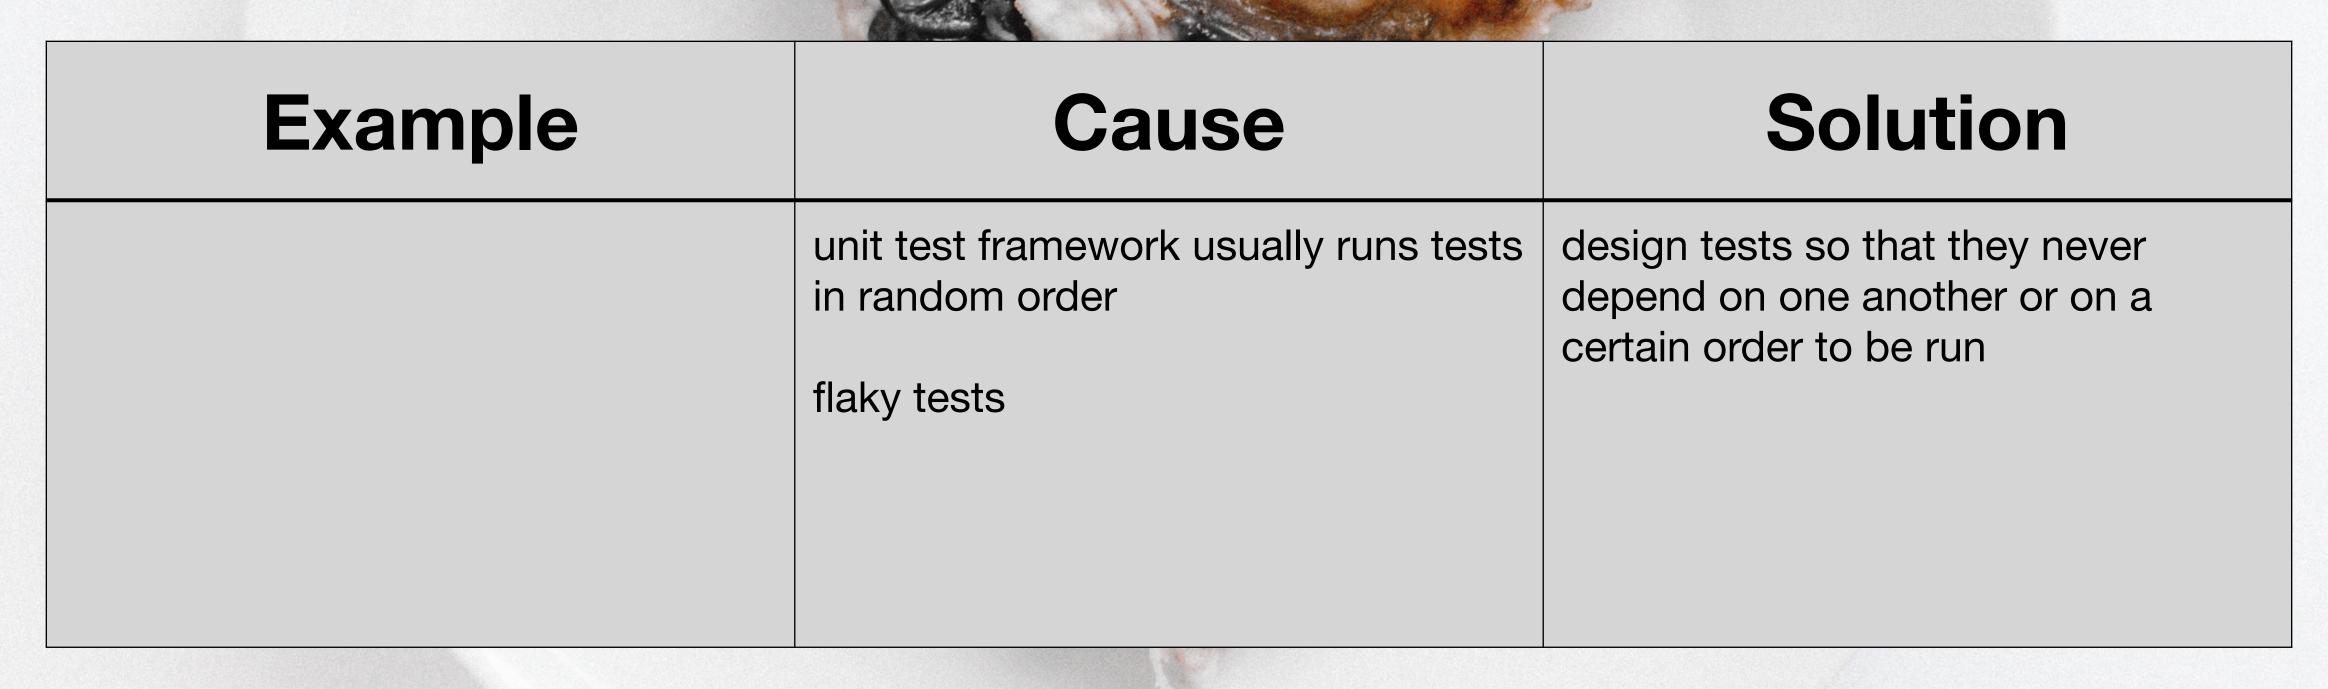

Example Cause Solution reading data from a database or from a list (that is not guaranteed to be sequential) order of items may differ on different machines make test not depending on the order of inputs or results

The Generous Leftovers

An instance where one unit test creates data that is persisted somewhere, and another test reuses the data for its own devious purposes. If the "generator" is ran afterward, or not at all, the test using that data will outright fail.

The Generous Leftovers
